On April 7, 2010, the Environmental Protection Agency (EPA) issued an Advance Notice of Proposed Rulemaking (ANPRM) entitled *Polychlorinated Biphenyls (PCBs); Reassessment of Use Authorizations*. In this ANPRM, the EPA proposes to reassess the existing PCB use authorizations under the Toxic Substances Control Act (TSCA), including the use authorization for PCBs in natural gas pipelines, air compressor systems and porous surfaces. As part of this reassessment, the EPA has proposed to revise and/or eliminate these use authorizations in a way that could significantly and dramatically impact natural gas pipeline operations. Natural gas pipelines have been subject to programs addressing PCBs for the past 30 years, starting with the EPA's Compliance Monitoring Program (CMP) in the early 1980's to the EPA's present comprehensive regulatory program, better known as the PCB Mega Rule promulgated in 1998.

The Interstate Natural Gas Association of America (INGAA) is a trade association representing virtually all interstate natural gas transmission companies operating in the United States. INGAA therefore has a direct interest in the EPA's ANPRM and accordingly has prepared comments in response. In support of these comments, INGAA has commissioned several independent experts to prepare "White Papers" providing key analysis of the complex issues raised by the EPA's ANPRM with respect to the presence of PCBs in the interstate natural gas pipeline system. These papers address pipelines and pipeline operations, the presence of residual PCBs in the pipeline system, the risks to health and the environment associated with PCB-impacted pipelines, the technical feasibility of removing diminishing concentrations of PCBs and the anticipated economic impacts resulting from the EPA's proposals.

S.S. Papadopoulos & Associates, Inc. was commissioned to examine chemical and physical properties of PCBs relative to the natural gas transmission system. This report reviews the relevant history of PCBs and their presence in pipelines and pipeline equipment, and the effectiveness of the transmission industry's success in removing PCBs from the pipeline systems since they were first regulated in the 1980's. While commissioned by INGAA in support of its comments, this report is an independent analysis, and its conclusions are based on the expertise of the author.<sup>1</sup>

---

<sup>1</sup> This report was written by Dr. Remy J.-C. Hennet, Principal at S.S. Papadopoulos & Associates, Inc., Bethesda, MD. Dr. Hennet holds a Ph.D. in geochemistry from Princeton University. He has more than 25 years of research and professional experience in the evaluation of the origin, fate and transport of chemicals in diverse environments. Dr. Hennet started working on PCBs issues in the interstate natural gas transmission system in 1989 and has worked on numerous PCB environmental cases over the last 20 years.

## **Executive Summary**

The physical and chemical properties of PCBs define how these materials move within the natural gas transmission system as well as the rate at which these materials can be removed from the system. The residual amounts of PCBs that remain in portions of the natural gas transmission system will continue to decrease over time, as companies continue to implement the removal of pipeline liquids. The management practices currently employed in the pipeline industry support the removal of PCBs without the introduction of extraneous solvents or disruption of the natural gas supply.

The Mega Rule and PCB use authorization have performed as expected for the interstate natural gas transmission industry. The vast majority of the PCB mass that was in the pipeline systems (i.e., lubricating oil) in the early 1980's has been removed. Large volumes of pipeline liquids containing PCBs have been collected from drips, scrubbers and filter/separators, and through pigging operations and targeted clean-ups. Large volumes of PCB waste have been disposed of according to all applicable regulations. Engineered control measures were implemented to remove PCBs from the affected locations. Pipeline segments and compressor stations that are still affected by PCBs are being monitored.

PCBs are soluble in pipeline liquids and their transport in the interstate natural gas transmission system is controlled by the formation and movement of these liquids. The transport of PCB gas in the vapor phase is immeasurable, non-detectable and entirely inconsequential in the natural gas transmission system.

Review of more than 6,000 data points reporting PCB concentrations in pipeline liquids samples collected from interstate natural gas transmission pipeline operators over the period 1981 to present shows a statistically significant decrease in PCB concentrations in recovered liquid samples over time in the interstate natural gas transmission system. The decrease has been substantial (i.e., one order of magnitude or more) and gradual. The decrease in PCB concentrations and PCB mass removal rate is due to the fact that it becomes more and more difficult to remove PCBs from the transmission systems as the remaining mass of PCBs becomes smaller and smaller over time.

Based on the data reviewed, PCB residuals remain in segments of the interstate natural gas transmission system. Over the period 2007 to present, approximately 50 percent of the pipeline

liquids samples analyzed for PCBs reported concentrations in the range 2 to 50 parts per million (ppm), 20 percent were above 50 ppm, and 30 percent were reported as non-detects.

Technologies such as solvent flushing and surfactant washing cannot remove all PCBs from the interstate natural gas transmission system. These technologies are essentially the same as the flushing with pipeline liquids which takes place naturally over time within the pipeline system. Solvent flushing and surfactant washing would introduce new chemicals into the transmission systems raising concerns about corrosion, material compatibility, and safety.

## **Section 1**

### **Introduction**

---

PCBs in the interstate natural gas transmission system were first characterized in the early 1980s. Under the supervision of the United States Environmental Protection Agency (EPA), a Compliance Monitoring Program (CMP) to control and remove PCBs, and to monitor the proper disposal of PCB waste was established. The CMP was replaced by the adoption of the PCB Mega Rule amendments in 1998 (Mega Rule). The interstate natural gas transmission pipelines affected by the presence of PCBs collected various data and information under the CMP and Mega Rule, including PCB concentrations in pipeline liquids, PCB concentration in the gas phase, and the volume of pipeline liquids collected and removed. This information is used and discussed in this report together with additional information provided by INGAA member companies that is deemed relevant to the understanding of the status and trends of PCBs in the natural gas transmission systems.

The 2010 Advance Notice of Proposed Rule Making<sup>2</sup> (ANPRM), published by EPA proposes to modify the current regulations and significantly changing the Mega Rule by first reducing the current use authorization from 50 ppm to 1 ppm, and subsequently eliminating the use authorization by 2020.

This paper is in support of INGAA's comments to the ANPRM. The paper presents information on the origin, fate, and transport of PCBs in the interstate natural gas transmission system.<sup>3</sup> The paper provides a short review of the properties of PCBs, Aroclors and Aroclor-based products, describes the physical processes that drive the fate and transport of PCBs in

natural gas transmission systems, the available data that document the overall rate of removal of these compounds from the impacted interstate transmission pipelines, the occurrence and interpretation of data trends, and a discussion of the limitations of clean-up technologies at removing PCBs from the interstate natural gas pipeline systems.

## Section 2

### Polychlorinated Biphenyls

---

Polychlorinated biphenyls (“PCBs”) represent a class of 209 individual chemical compounds that were synthesized by the chlorination of biphenyl with anhydrous chlorine under controlled conditions in the presence of a catalyst.<sup>4</sup> PCBs are described by the generic chemical formula  $C_{12}H_{(10-n)}Cl_n$ , where Cl is for chlorine, C for carbon, H for hydrogen, and n for the number of chlorine atoms in the molecule (n = 1 to 10). The structure of PCBs is illustrated below; the numbers and primed numbers define the location of the chlorine atoms on the biphenyl molecular frame.

**Figure 1: Polychlorinated Biphenyls -- Molecular Structure**

PCBs have highly useful properties that include their chemical and physical stability (or inertness), electrical insulating properties, low vapor pressures, high boiling points, thermal conductivities, and flash points. For this reason, PCBs were commercially produced and used in large quantities in the United States between 1929 and 1977.<sup>5</sup> PCBs were produced as mixtures

---

<sup>4</sup> Individual constituent PCB compounds are called “congeners”, and sets of PCB molecules with the same number of chlorine atoms are called “homologs”. The term “isomers” is at times used to describe the congeners of a given homolog series.

<sup>5</sup> During that period of time Monsanto, the sole commercial manufacturer of PCBs in the United States produced a total of approximately 1.25 billion pounds of PCBs. (Erikson, M., 1992; Analytical Chemistry of PCBs).

of congeners to confer desired properties for various applications. The mixtures were sold under the registered trade mark of “Aroclor” followed by a 4 digit code. PCB Aroclors were indicated by “12” for the number of carbon atoms in biphenyl, followed with the percentage of chlorine in the product; for example, Aroclor 1242 is a PCB product containing 42 percent chlorine by weight.<sup>6</sup>

Aroclors are complex mixtures of individual PCB congeners and were used in the formulation of a large variety of products. Several products were formulated with more than one Aroclor mixture to confer the product with desired properties. Aroclor 1242 was the most commonly used Aroclor, representing slightly more than 50 percent of the total production in the United States. PCB Aroclors were used in the natural gas industry due primarily to their high flash point, low flammability, and chemical stability. The main PCB products used in interstate pipelines were formulated with Aroclors 1242 and 1248 (i.e., lubricants for gas compressors), and Aroclor 1254 (i.e., lubricants for air compressors), Aroclor 1260, and Aroclor 1268 (i.e., valve sealants and lubricants).

Aroclors are soluble in non-polar liquids such as hydrocarbon fuels and oils (solubility values in the percent range) but are virtually insoluble in water (solubility values in the part per billion level). Aroclors exist as liquids or solids at ambient temperature, have very low vapor pressures and are therefore non-volatile.<sup>7</sup> Aroclors have a strong affinity for organic materials<sup>8</sup> into which they tend to absorb, and solid surfaces onto which they tend to adsorb. Organic materials for which Aroclors have a strong affinity include lube oils, greases and sealants, plastics, rubber, paints, and coatings. Metal and solid surfaces that come in contact with the natural gas stream

---

<sup>6</sup> The exception to this convention is for Aroclor 1016, a PCB Aroclor which started to replace Aroclor 1242 in the early 1970's; Aroclor 1016 was produced by distillation of Aroclor 1242 and represents a narrow cut of Aroclor 1242.

<sup>7</sup> For comparison, the vapor pressure of volatile compounds such as hexane or benzene, are 5 or more orders of magnitude higher than the value for Aroclor 1242.

<sup>8</sup> As shown on Table 1, Aroclors have very high octanol-water partition coefficients ( $\log K_{ow}$ ) indicating a strong affinity for hydrophobic materials such as oils, fuels, greases, plastics, rubbers, etc.

become coated with a hydrocarbon film (i.e., lube oil, and/or condensate components) regardless of whether or not synthetic protective coatings have been applied for corrosion protection. Aroclors tend to absorb and accumulate on these surfaces and become a component of the film that coats the solid surfaces in the interior of pipelines.

Representative properties of selected PCB Aroclors are summarized in Table 1.

**Table 1 -- Representative Properties of Selected Aroclors**

	Vapor Pressure (psi at 25°C)	Boiling Range (°F)	Average Molecular Weight (g/mol)	Density (g/cm <sup>3</sup> )	log Kow
<b>Aroclor 1242</b>	0.00000750	617 – 691	264	1.35	5.30
<b>Aroclor 1248</b>	0.00000123	644 – 707	294	1.40	6.10
<b>Aroclor 1254</b>	0.00000038	689 – 734	328	1.50	6.50
<b>Aroclor 1260</b>	0.00000004	725 – 788	374	1.60	6.90

Values selected from MacKay et al. (2006)

PCB Aroclor mixtures were used to formulate and manufacture a large variety of industrial and residential parts and products. These parts and products included dielectric fluids (transformers, capacitors, fluorescent light ballasts, etc.), oils and lubricants (compressors, turbines, hydraulic systems, heat transfer systems, vacuum pumps, casting agents, cutting oils, etc.), plasticizers (rubbers, gaskets, O-rings, synthetic resins, carbonless paper, etc.), printing inks, paints, coatings, waterproofing agents, sealants, caulking compounds, adhesives, casting waxes, wax extenders, de-dusting agents, insulation materials, flame retardants, pesticide extenders, wire coatings, PVC tubing, floor lacquers, and many others.

Because of their widespread and various uses and properties that confer environmental persistence, PCBs rapidly became ubiquitous in the global environment.<sup>9</sup> More than 30 years after being banned in the United States, PCB residuals remain detectable and widespread.

The interstate natural gas transmission system does not presently use PCBs, but the presence of PCB residuals in impacted pipelines is a legacy from a foregone period that ended more than 30 years ago.

## **Section 3**

### **Introduction of PCBs into the Interstate Natural Gas Transmission System**

---

Compressor stations are part of the pipeline system and serve the main purpose of re-compressing the gas stream to keep it moving through the transmission system to its destination. Compressor stations host air and gas compressors, drivers, pig launchers and/or receivers, and other pertinent equipment. A major source of PCB contamination of natural gas transmission piping in the interstate natural gas pipeline system was the use of PCB-based lubricating oil in centrifugal compressor units.<sup>10</sup> Only some interstate natural gas transmission systems used PCB-containing oils in their centrifugal compressors. For the pipelines that did, the use was limited to a subset of their centrifugal compressors.

While PCB containing lubricants were primarily utilized on some drivers (e.g. turbines) because of resistance to ignition at high temperatures (high flash point), some of these compressor units shared common oil reservoirs between the driver and compressor. During start-up and when compressing the gas stream, centrifugal compressors are designed to release a small amount of oil into the compressor housing seal that is directly connected to the natural gas transmission pipeline; this oil transfer occurs to assist compressor seals from leaking natural gas to the atmosphere. The amount of oil thus transferred depends on the design of the compressor equipment and its mode of operation. Compressors do not operate continuously and shut-down and start-up events occur periodically. A typical centrifugal compressor contains approximately 1,000 gallons of oil (500 to 2,000 gallons, depending on horsepower, age, and manufacturer).

---

<sup>10</sup> Natural gas pipeline systems rely on several types of compressors (i.e., reciprocal positive displacement compressors, centrifugal compressors, air compressors, etc.); compressors are powered by drivers (turbines, engines, etc.).

This equipment consumes several hundred gallons of oil per compressor per year during routine operation. The oil is consumed principally by combustion; new oil is added when needed.

Parts and products such as gaskets, seals, o-rings, coatings, plastics, sealants, lubricants, etc, may have contained PCBs prior to 1977 and could therefore have been potential secondary sources of PCBs in pipeline systems. The relative PCB contribution from such sources would have varied over time, from interstate transmission pipeline to interstate transmission pipeline, as well as from compressor station to compressor station within an individual interstate transmission pipeline.

Various commercial products, including sealants, were formulated with Aroclors prior to the PCB ban. Sealants were used in valves. Sealants packaged in both sticks and cans were commonly used for pipeline maintenance and could have contained PCBs prior to the commercial ban.

Many parts and products used in pipeline systems were not formulated or manufactured with Aroclors, but may have inadvertently contained small amounts of PCBs. The historical off-site maintenance of refurbishment of equipment is an example of an inadvertent pathway through which PCBs could have entered the interstate transmission system.

## **Section 4**

### **Transport of PCBs in the Interstate Natural Gas Transmission System**

---

For the interstate natural gas transmission system, this report considers two theoretical modes of transport for PCBs; these are:

- in the liquid phase as dissolved in pipeline liquids; and
- as PCB gas in the vapor phase.

These two theoretical modes of transport are evaluated below and their relative importance is determined, within a reasonable degree of scientific certainty, using the available data. The nature of natural gas condensate and pipeline liquids is discussed through a review of the processes that lead to the formation of condensate and pipeline liquids and review of the available data..

### **Formation of Condensate and Pipeline Liquids**

Pipeline liquids<sup>11</sup> are made of condensate and oil and/or lubricants from mechanical operations. Natural gas condensate is generated from the condensation of heavier hydrocarbons that are present in the gas stream primarily as a result of the lowering of temperature.<sup>12</sup> Liquids condense out of the gas stream wherever the pressure and temperature conditions are such that both gas and liquid can coexist, as illustrated in Figure 2. Interstate natural gas transmission systems that were constructed prior to the end of the PCB period of use (late 1970s) typically

---

<sup>11</sup> In this paper, pipeline liquids refer to hydrocarbon condensate that drops out by condensation from the natural gas, and oils, greases, and/or lubricants that enter the pipeline from operations and become mixed with the condensate. Pipeline liquids, as discussed/defined herein do not include the water that is also typically present as a liquid in pipelines since PCBs are virtually insoluble in water; thus pipeline water is not discussed further.

<sup>12</sup> This is described in the literature, see for example: White Paper on Liquid Hydrocarbon Drop Out in Natural Gas Infrastructure (LGC+ Liquid Hydrocarbon Drop Out Task Group, February 28, 2005).

operate within a pressure range of approximately 600 to 1,100 psi. Newer pipelines can operate at higher pressures. Temperature of the gas along the pipelines varies and tends to approach the temperature of the ground or the water bodies through which they pass. Temperature increases to 125°F or more at the discharge side of compressor stations occur due to re-pressurization of the gas stream. Consequently, the gas stream typically experiences several heating and cooling cycles as it is transported through the pipelines.<sup>13</sup>

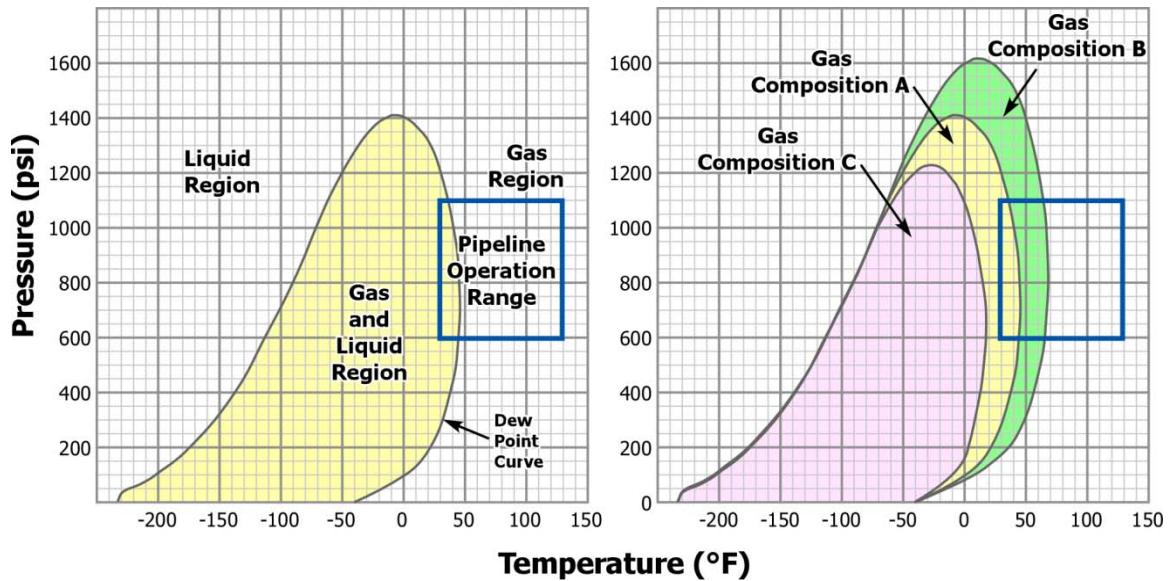

The position of the “gas and liquid region” on a pressure-temperature diagram (the temperature and pressure at which liquid hydrocarbons drop out of the gas stream) is a function of gas composition and is more dependent on temperature than pressure under pipeline operating conditions. This is known as the “dew point curve” and illustrated on Figure 2 for a range of natural gas compositions. As shown on the figure, different gas compositions may or may not generate condensate over different temperature and pressure ranges. Gas Composition A and B, would generate some condensate while Gas Composition C would not. Pipeline segments that do not contain condensate are referred to as “dry” segments.

Small compositional changes of the natural gas shifts the position of the dew point curve, and pipeline operators monitor and continuously measure relevant parameters that allow for the calculation and location of the curve on pressure-temperature diagrams. These parameters are closely monitored because they are important indicators of overall gas quality.

Condensate liquids are low viscosity (less than 1 centipoise), low density (less than 0.7 mg/L) mixtures of light hydrocarbons from the natural gas. The molecular weight of the compounds that form natural gas condensate typically is between 70 to 120 grams per mole. Oils, greases, and residual PCBs have a higher viscosity and higher molecular weight than condensate liquids, but are soluble in condensate. Mixed together, these products and the natural gas condensate form the pipeline liquids.

---

<sup>13</sup> For example, every 4 hours for a gas stream traveling at 20 miles per hour between stations located 80 miles apart.

**Figure 2: Typical pressure-temperature phase diagram for natural gas**

Absent pipeline liquids or condensate, PCBs and other low vapor pressure and high viscosity compounds (i.e., greases, lube oils, etc.) are immobilized by adhering to the interior pipeline walls.

## Pipeline Liquids

PCBs become dissolved in pipeline liquids in areas where condensate forms (e.g. certain pressure/temperature conditions), and it accumulates at drips, valve seats, and other low spots along the pipeline. Periodically, these accumulated pipeline liquids are removed and disposed of properly.

PCBs can be mobilized with pipeline liquids when sufficient liquids accumulate in geographic low points as pipeline liquids pool within the pipe. There can be accumulations in low sections of the pipeline to the extent that the pipeline liquids form liquid “slugs” that move to the next geographic low point on the pipeline. Eventually this sporadic process moves the

liquid slug to a liquid removal device (e.g., drips, scrubbers, or separators) where these accumulated pipeline liquids are removed and disposed of properly.

Pipeline companies run devices known as “pigs” through pipeline segments to clean, inspect, and remove incidental liquids in the pipeline. Pigging of lines is a standard part of pipeline maintenance and operations, and is identified in the 1981 CMP program submissions to EPA of some pipeline companies as a PCB removal procedure. The extent of pigging has increased significantly in recent years due to the requirements of the DOT’s Pipeline Integrity Management Program.<sup>14</sup> Under the program, as discussed below, pipelines are required to periodically assess the integrity of their lines. The most efficient and effective way to do this is to run “smart pigs,” which are electronic internal inspection devices that record pipeline conditions, such as pipeline deformations and metal loss.<sup>15</sup> Consequently, INGAA members modified their pipeline systems to allow pigging. Prior to running a smart pig, pipeline companies must run a series of scrubber pigs through the system to clean and remove free liquids and debris to ensure the smart pig sensors make proper contact with the interior surface of the pipe.<sup>16</sup> During cleaning operations, the scrubber pig scrapes the interior of the pipeline walls. In the process, incidental liquids are pushed in front of the pig and mixed with debris, which may contain PCBs. Pipeline liquids act as a solvent to remove PCBs from the pipeline’s internal walls. Pigging is a very effective way to sweep liquids from the pipeline for ultimate disposal. For impacted pipelines, pigging leads to the gradual removal of PCBs from the interior of the pipeline. Pigging operations may not result in the full removal of the PCBs adhering to the pipeline walls and certain segments of the pipelines cannot be pigged due to design conditions (e.g., pipe diameter changes, valve configurations, river crossing designs, etc.). In those

---

<sup>14</sup> See generally C.F.R. Part 192.

<sup>15</sup> Note, however, that not all pipeline segments are “piggable.” See Pipeline Knowledge & Development, The Interstate Natural Gas Transmission System: Scale, Physical Complexity and Business Model (Aug. 2010).

<sup>16</sup> Pipeline Knowledge & Development. The Interstate Natural Gas Transmission System: Scale, Physical Complexity and Business Model (Aug. 2010).

segments of pipeline containing PCBs at concentrations at or above 50 ppm, pipeline companies sample the liquids at each pig receiver trap or historical liquid collection point to monitor the PCB levels within the system over time.

## **PCB Gas in the Vapor Phase**

The PCB concentration data collected in the interstate natural gas transmission system also includes analytical results for 207 gas stream samples collected between 1982 and 1997 in systems affected by PCBs. These samples were collected with Florisil tubes according to EPA procedures and guidance.<sup>17</sup> PCBs were never detected in the gas stream of the interstate natural gas transmission system at detection limits as low as 0.1 ug/m.<sup>3</sup> The collection of gas samples with Florisil tubes captures PCB vapors as well as any mist or particulates that might be present in the gas stream. This data confirms that PCBs are not detectable as gases in the vapor phase under the physical conditions at which interstate pipeline systems operate.

A theoretical PCB concentration in the vapor phase at equilibrium with the pipeline liquids can be estimated through a mathematical calculation using Raoult's Law and the Ideal Gas Law under conditions that are representative of a typical interstate gas pipeline impacted by PCBs. However, such a calculation would not be considered representative because instantaneous equilibrium between the liquid phase that contains PCBs and the vapor phase that flows above the liquid phase is not reached for the following reason:

- The mathematical calculation assumes instantaneous equilibrium between the liquid phase that contains PCBs and the vapor phase that flows above the liquid phase. In reality, equilibrium is not reached or approached instantaneously and the actual vapor

---

<sup>17</sup> Validation of a Method to Measure Polychlorinated Biphenyls in Natural Gas Pipelines. EPA-600/4-81-048, June 1981.

vapor phase PCB concentration is therefore much less than the theoretically calculated amount.

- First, the natural gas stream moves through the pipeline typically at 10 to 30 miles per hour (about 15 to 45 ft/s). At a 20 miles per hour gas stream velocity, it would take only 3.3 seconds for the gas to pass over a 100 foot liquid pool. This amount of contact time is not sufficient for PCB concentrations to equilibrate between the gas and liquid phases.
- Second, PCB molecules could volatilize only from the exposed surface of the pipeline liquids. As PCB concentrations become depleted in the liquids close to the surface, the PCBs would have to be replaced by PCB diffusion towards the surface from the interior pipeline liquids. Diffusion is a very slow process. There simply is not sufficient time for equilibrium to be reached between the liquid and gas phases, and for PCBs to diffuse and volatilize into the natural gas stream.

A more representative PCB concentration in the vapor phase could theoretically be calculated through the use of mass transfer coefficients for PCBs in the liquid and gas phases under the pressure and temperature conditions of the pipeline, and using pipeline specific parameters (i.e., pipeline cross sectional area, pipeline liquids pool surface area, pipeline liquids thickness, natural gas velocities). Mass transfer coefficients that would apply to an interstate gas pipeline are not available from the literature and this refined calculation cannot be performed.

Data from the analysis of 207 gas samples are consistent and support the conclusion that PCB gas in the vapor phase in the interstate natural gas transmission system is immeasurable and non-detectable. The transport for PCBs in the natural gas transmission system is controlled by the formation and movement of pipeline liquids; not by PCB gas in the vapor phase.

## **Section 5**

### **Removal of PCBs from Natural Gas Transmission Systems**

---

Once inside a natural gas transmission pipeline, PCBs mix and blend with liquids (i.e., oils, condensate, lubricants, etc.) that are periodically removed from the pipeline system. Other PCBs gradually diffuse and accumulate into hydrophobic materials (i.e., internal coatings, gaskets, o-rings, greases, sealants, lubricants, etc.), and adhere to various coatings and solid surfaces. Mixing and blending can occur rapidly but diffusion processes are very slow in comparison. The diffusion rate is proportional to the concentration gradient; the higher the concentration gradient, the faster diffusion proceeds. The diffusion of PCBs into hydrophobic materials was therefore greatest during the loading and distribution period when PCB-containing products were actually being used and, therefore when maximum concentration gradients were in place.

The reversal of diffusion to remove PCBs from the hydrophobic materials is slower and becomes gradually slower over time because the concentration gradient that drives the PCB removal becomes gradually smaller. This result implies that the removal of PCBs in hydrophobic materials is expected to be much slower and to last much longer than the loading period.<sup>18</sup>

PCB products were commercially available in the United States starting in 1929, before construction of most interstate natural gas transmission pipelines. Due to the widespread usage of lubricants containing PCBs, it is possible that pipelines constructed prior to the 1970's were exposed to PCB-containing parts or products. In the interstate natural gas pipeline systems that used PCB oils, PCBs likely diffused into pipeline materials under maximum concentration gradients.

---

<sup>18</sup> For example, assuming that the loading period for hydrophobic materials in a pipeline system lasted for 20 years, the time to diffuse the PCBs out from these materials would be much longer than 20 years.

The removal of PCBs from the interstate natural gas transmission systems is limited by the reversal of the loading and distribution processes. The reversal of the loading process started in the 1970's, with the phasing out of PCB products and the removal of PCB-based oils from compressors and other equipment pieces. In practice, the reversal of these processes can be summarized in three categories for simplicity: PCB removal from the draining of equipment; PCB removal from normal pipeline operations; and PCB removal through control measures and targeted clean-ups.

## **PCB Removal from the Draining of Equipment**

In the early 1970s, PCB oils started to be phased out and by the early 1980s, PCB-based oils had been mostly removed from the lubrication system of the natural gas compressors. Removal was achieved by draining, flushing and replacing the PCB oils with non-PCB oils. Draining of large pieces of equipment that contained thousands of gallons of PCB oils resulted in the removal of the large majority, but not all, of the PCBs that existed in the interstate natural gas transmission system.<sup>19</sup>

Flushing of PCB-impacted natural gas compressor systems was typically conducted repetitively in the 1980s to remove PCB residuals and meet or maintain the 50 ppm regulatory criterion. Repetitive draining and flushing of equipment of the complexity of lubricating systems removes very little PCB mass, but can decrease PCB concentrations to acceptable levels.<sup>20</sup> The rebound in PCB concentrations in a purged lubrication system is due to the slow and gradual, sporadic leaching of PCB residuals in the interior of the equipment. For complex pieces of

---

<sup>19</sup> PCB-based oils used in centrifugal compressors were manufactured to contain approximately 90 percent PCBs by weight. Draining of 1,000 gallons of PCB oil with a density of 1.4 g/cm<sup>3</sup> removes approximately 10,000 pounds of PCBs.

<sup>20</sup> Draining of 1,000 gallons of lube oil with a density of 0.9 g/cm<sup>3</sup> and a PCB concentration of 50 ppm removes approximately 0.2 pounds of PCBs.

equipment like compressors, repetitive draining and flushing remove the vast majority of the PCB mass but never all of the PCB residuals.

## **PCB Removal from Normal Pipeline Operations**

A large portion of the mass of PCBs that was introduced in the interstate natural gas transmission system was removed during and shortly after the period of PCB use. PCBs were removed through normal operations; in particular through the removal of large volumes of pipeline liquids from liquid collection points along the pipelines. Compressor stations are equipped with filter separators, scrubbers or mainline drips and accumulation tanks that remove pipeline liquids from the gas stream prior to recompression to minimize damage to equipment. Other measures to remove pipeline liquids can include mainline drips downstream of compressor stations or at low points, periodic pig runs to remove pipeline liquids where feasible, and meter station drip pots. PCB concentration in pipeline liquids started to be monitored in the early 1980s with concentrations in the order of several thousand parts per million in some affected pipeline systems (Versar 1984, Table Z1).<sup>21</sup>

## **PCB Removal through Control Measures and Targeted Clean-up**

The primary methods employed by the interstate natural gas transmission industry to reduce the levels of PCBs in the pipeline systems are to remove and properly manage pipeline liquids. As part of the former CMP, natural gas pipeline companies that were impacted by PCBs submitted PCB liquid removal plans to the EPA. After review, these liquid removal plans were approved by EPA. The CMP plans, as well as the “use authorization” provisions of the PCB Mega Rule, required use of engineering controls, among other things, for the purpose of removing PCB liquids from the system.

<sup>21</sup> Versar, May 2, 1984; Exposure Assessment for Polychlorinated Biphenyls. US EPA Contract No 68-01-6271.

Compressor stations are equipped with engineered measures that include scrubbers and liquid separator units to remove pipeline liquids from the gas stream prior to recompression. Pressure and temperature conditions at these locations are the most advantageous for the formation of natural gas condensate. The presence of pipeline liquids in either reciprocating or centrifugal compressors can cause extensive mechanical damage since liquids are not compressible, so it is an advantageous, operational necessity to remove liquids from the gas stream before compression.

Control measures also include periodic pig runs to remove pipeline liquids where feasible. Interstate natural gas transmission systems affected by PCBs also implemented additional, targeted clean-up measures. Targeted measures can include meter inspections and cleaning, drip flushing, drip removal, cleaning of filter housings, cleaning of valves, cleaning of tanks and other equipment found to contain PCB residuals. Some PCB containing equipment may also have been removed, decontaminated or disposed in accordance with the applicable Mega-Rule requirements and regulations.

The PCB concentration data collected in the interstate natural gas transmission system includes analytical results for 6,106 pipeline liquids samples collected between 1981 and the present. The samples are representative of pipeline liquids collected in accumulator tanks, mainline drips, meter station drip pots, filter separator units, pig receivers, and scrubbers in the interstate natural gas transmission systems that are affected by PCBs. The data is provided in Appendix I and illustrated in Figure 3. In Figure 3, measured PCB concentrations in pipeline liquids are presented on a logarithmic scale: the blue line represents the yearly median PCB concentrations;<sup>22</sup> the red line represents the 50 ppm concentration level (current PCB use authorization); and the green line represents the year 1998 (beginning of the Mega Rule period).

---

<sup>22</sup> A yearly median value represents the median PCB concentration value for all measurements for a given year (1981 to present); non-detects are considered at the reported detection limit.

The data set demonstrates or supports the following observations and conclusions on the removal of PCBs from the interstate natural gas transmission systems that are affected by PCBs:

- The impacted transmission pipelines have been monitored starting in the early 1980's to the present for the presence of PCBs in pipeline liquids.
- The 6,106 points data set indicates that the overall PCB concentration in the interstate natural gas transmission system is decreasing over time, having started in the thousands of ppm range in the early 1980's, and decreasing to the tens of ppm range at present. However, the scattered data shows that there are numerous segments and components in the system that still exceed the 50 ppm level.
- PCB concentrations are scattered over about 3 orders of magnitude at all times during the period of record. The scattering represents the range of PCB concentrations that are typically encountered in the transmission system. The scattering is explained by the complexity and scale of the system and the variability of the sampling locations and frequencies.
- The majority of the PCB concentration data points that represent recent years fall below the 50 ppm use authorization level; however, PCB concentrations remain above 50 ppm in a substantial subset of the samples.
- The data does not support that the interstate natural gas transmission system can reduce PCB concentration levels to less than the current regulatory standard of 50 ppm either now or in the foreseeable future.
- The data support that, in areas of the transmission system where PCB concentrations exceed 50 ppm, PCBs are being actively removed from the system and PCB mass is being reduced.
- The shape of the data series indicates that the rate of decreasing concentrations was faster early on and slowed down gradually toward the present (see exponential curve fit on Figure 4 as discussed below). This variation in the rate of decrease reflects the fact that it becomes harder and harder to remove PCBs as the residual PCB mass continues to diminish. This is consistent with the conclusion that the removal of PCBs is controlled and limited by processes that are driven by concentration gradients (i.e., diffusion processes).
- Starting in approximately 2006, with the advent of the PHMSA Pipeline Integrity Management Program, the data indicate a rise in the yearly median PCB concentration levels for the period 2007 to the present. The rise is believed to be

associated with the change in pipeline integrity requirements and the increase of pipeline pigging activity which likely dislodged PCB-containing material from the interior of the pipeline wall. This rise does not represent a reversal in the general trend of PCB removal from the pipeline system.

An analysis was conducted on the 6,106 points pipeline liquids data set shown in Figure 3 to test for the occurrence of a statistically significant trend. Both parametric (ordinary least-squares, OLS) and non-parametric (Mann-Kendall Theil) statistical trend analyses were conducted following the methodology outlined by Helsel and Hirsch (2002).<sup>23</sup> Results show that a decreasing trend is supported by the data set; the decreasing trend is statistically significant at a p value better than 0.01 (i.e., more than 99 percent probability that the trend is real) for both the parametric and non-parametric tests.

## **Section 6**

### **Residual PCBs in the Interstate Natural Gas Pipeline Systems**

---

Today, residual PCBs in the interstate natural gas transmission system represent a very small fraction of the PCBs that ever entered the affected systems. As discussed in the previous section, the great majority of the PCBs that entered the interstate natural gas transmission system were removed during the period of PCB use, the period of PCB phase-out, and the period during which compressors and other pieces of equipment were drained and flushed. Residual PCBs in the natural gas transmission system were evaluated utilizing the available data and through a case study for a single compressor stations and pipeline segment affected by PCBs.

#### **Available Data**

Typical concentrations measured in pipeline liquids collected in the early 1980s were reported in the thousands of parts per million (Versar 1984, Table Z-1). By comparison, present concentrations in these same systems have decreased by one or more orders of magnitude down to the tens to a few hundreds of parts per million range, as shown in Figure 3. The yearly median values for the 6,106 points data set shown in Figure 3 (blue line) are below the 50 ppm level (red line), however, numerous PCB concentration values remain above 50 ppm. For example, considering only the recent data available for analysis (2007 to present; 829 samples), approximately 20 percent of the pipeline liquids samples analyzed for PCBs reported concentrations above 50 ppm, 50 percent were in the range 2 to 50 ppm, and 30 percent were reported as non-detects.

The statistically significant decreasing trend for PCB concentrations that was discussed previously for the 6,106 points data set can be represented by the yearly median concentration values, as shown in Figure 3. The yearly median PCB concentrations can be fitted to a simple exponential function, as shown in Figure 4. The exponential fit is reasonable for the data set but does not capture fully the higher decrease in PCB concentrations observed in the early 1980s.

However, the exponential fit is sufficient to support the conclusion that PCBs will remain in the affected interstate natural gas transmission systems at the ppm level for decades to come.

A small amount of PCB residuals remain in certain compressors and drivers that are in use in the interstate natural gas transmission system, even though those pieces of equipment were drained and flushed repetitively to remove PCB oils in the 1970s and 1980s. The PCB concentration in the lubricating oil is periodically measured to monitor the potential rebound in PCB concentrations over time; PCB concentrations in some affected compressors remain in the low ppm range, even after repetitive purging of the oil.

## **Case Study**

A case study of a data set available for a single compressor station in an interstate natural gas transmission system affected by PCBs can serve as an example of the progress made at removing PCBs. The data is illustrated in Figure 5a, b, and c. The data in Figure 5 comes from the analysis of pipeline liquid samples from one source control accumulator tank that served to store pipeline liquids collected at the station over a period of several years (1996 to 2007). Figure 5a represents the measured PCB concentrations over time and the yearly median concentration values connected by a line as an overlay. Figure 5b shows the yearly volume of pipeline liquids collected in the accumulator tank. Figure 5c the calculated yearly PCB mass removal rate at the compressor station. The yearly mass removal rate is calculated by multiplying the median concentrations (Figure 5a) by the volume of pipeline liquids (Figure 5b). The case study demonstrates or supports the following:

- PCB concentrations in pipeline liquids have been gradually decreasing starting from the hundreds of ppm level in 1996-97, down to the tens of ppm level in 2006-07; a decrease of about one order of magnitude.
- The recent values for PCB concentrations are between 10 and 50 ppm.
- The yearly volume of pipeline liquid collected varies from year to year but appears to generally decrease over time.

- The mass of PCBs removed annually has decreased gradually or exponentially over time from approximately 1 kilogram per year (2 lbs/yr) in 1996-97, down to a few grams per year (i.e. 0.1 lbs/yr) in 2005-07.

The yearly PCB mass removal rate is reasonably well fit by a first order exponential function (Figure 5c), indicating that the removal of PCBs from the pipeline segment is controlled by processes that depend on concentration gradients (i.e. diffusion processes). By integration to infinity of the exponential function fitted to the rate of PCB mass removal, one can estimate the mass of PCBs that remains to be removed from the system represented by the compressor station in the case study. The estimated mass of PCBs that remains to be removed is in the order of a few tens of kilograms at the case study's compressor station.

Results from the case study are similar to the results for the 6,106 measurement data set that represent the entirety of the affected transmission systems and support the same conclusions as to the removal of PCBs from the interstate natural gas transmission systems: progress is substantial, but it is slow and gradual, as it becomes harder and harder to remove smaller and smaller amounts of PCBs from the systems. It is also important to notice that the concentration of PCBs in pipeline liquids at the case study compressor station remains close to the 50 ppm use authorization level. Assuming that PCB concentrations and residual mass will continue to decrease as modeled by an exponential decay, it can be predicted that it will take several decades for concentrations in pipeline liquids to drop below the ppm level at the case study compressor station.

In summary, despite the substantial progress made in the removal of PCBs from the interstate natural gas transmission systems over the past three decades, residual PCBs remain present at the ppm level in the affected transmission systems. PCBs are removed gradually but slowly, and the removal rate decreases as less and less PCBs remain in the systems. This indicates that the removal of PCBs is controlled by processes that are dependent on concentration gradients (i.e., diffusion processes). The data for pipeline liquids PCB concentrations in the overall interstate natural gas transmission systems, and the data for PCB concentrations, volume of recovered

pipeline liquids and the calculated mass removal for the case study at the compressor station scale are all consistent and support these conclusions and interpretation.

## **Section 7**

### **Existing Technologies Cannot Remove all PCBs from Natural Gas Pipelines**

---

PCBs are being removed from the interstate natural gas transmission systems through the collection of pipeline liquids, control measures, and targeted clean-ups, as discussed above. A trend analysis shows that PCBs are decreasing slowly over time. The data indicate that PCB residuals at concentrations in the tens to hundreds of ppm, or more remain present in portions of the transmission systems.

The removal of PCBs from the interstate natural gas transmission systems cannot be accelerated at will, absent employing the extreme scenario of system replacement. The interstate transmission system is very complex at the scale of relevance to PCB removal. Under these circumstances, it is expected that the removal of PCBs from the interstate natural gas transmission system would be gradual and slow. Ultimately, diffusion processes limit the rate of removal; these types of processes cannot be substantially accelerated in the interstate natural gas transmission system (i.e., affected systems cannot be heated to high temperatures to accelerate diffusion into pipeline liquids).

Several technologies have been proposed to remove PCBs from affected interstate natural gas transmission systems, among those are solvent flushing and surfactant washing technologies. These technologies have been considered by some interstate pipeline operators and some pilot testing has been conducted. The results of this testing suggest that certain solvents and surfactants can be effective at cleaning impacted parts and/or pipes, but none of these technologies can remove all of the PCBs from an actual pipeline system that includes connecting seals, drips, coatings, and the intricate piping system at compressor stations. Furthermore, these technologies rely on introducing compounds that would not otherwise be present in the pipeline

environment, which can create major problems for operations, including concerns about corrosion, material compatibility, safety, and air emissions from volatile solvents.

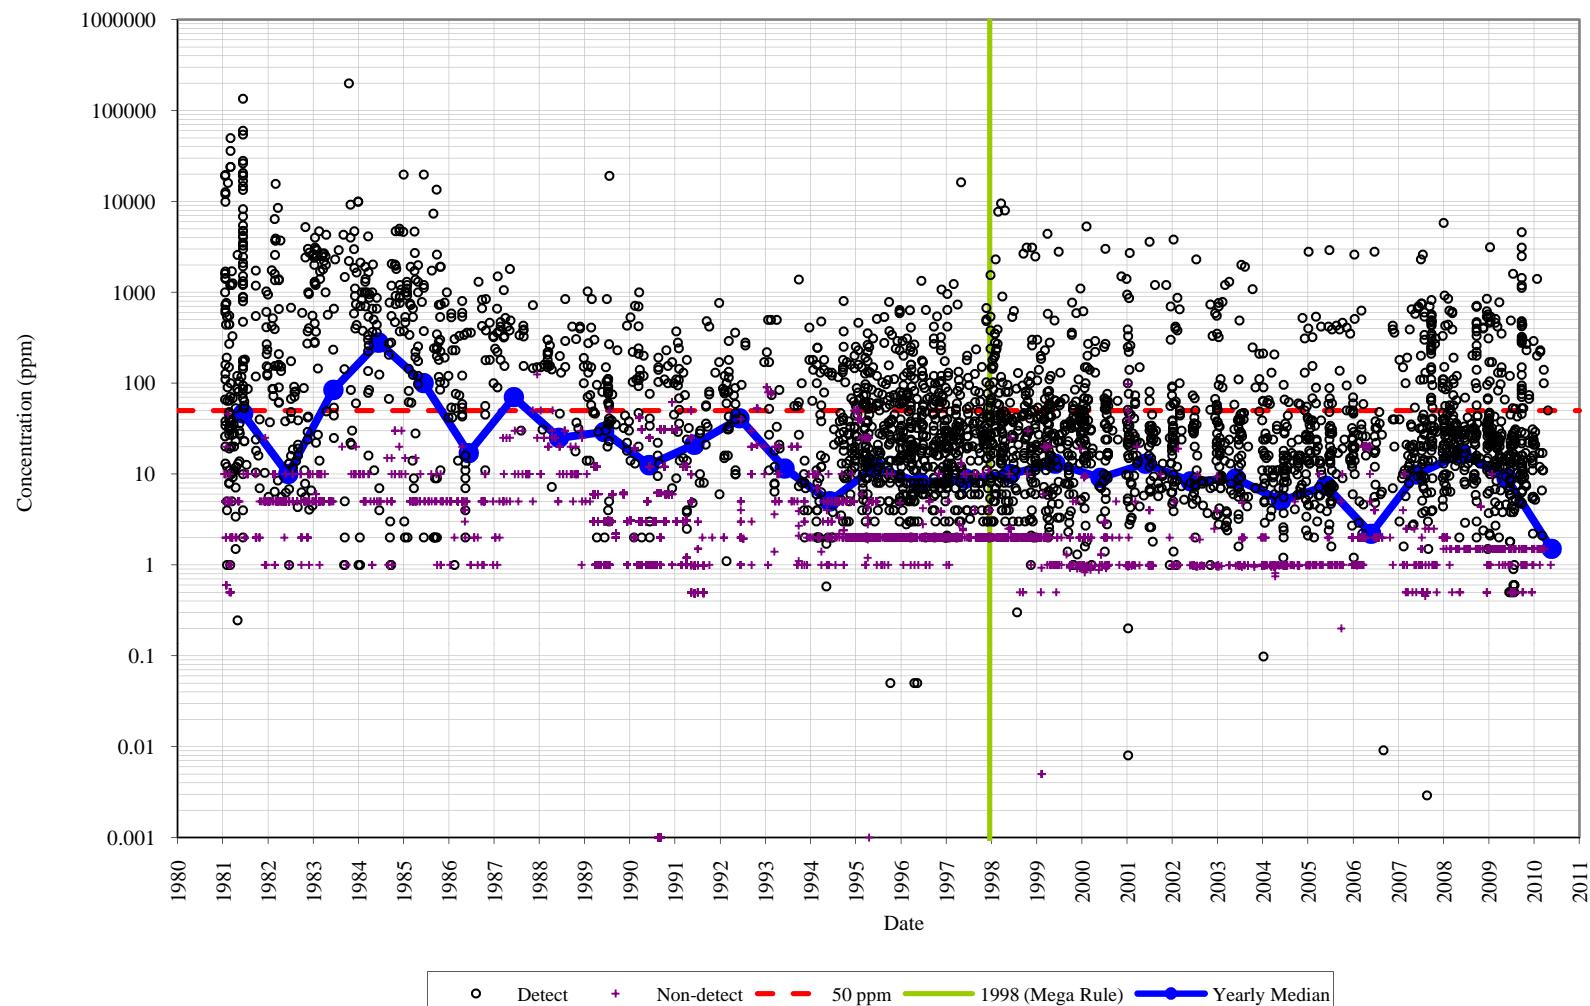

Solvent flushing and surfactant washing technologies do not represent a substantial improvement upon the technologies that are presently used and implemented by some interstate natural gas transmission systems. Solvent flushing or surfactant washing is similar to the pigging operations that are being conducted to remove pipeline liquids from the systems. Pipeline liquids are mostly made of condensate from the gas stream, and condensate is a solvent in which PCBs are soluble.

Assuming, for the purpose of discussion only, that solvent flushing and/or surfactant washing technologies could substantially accelerate the removal of PCBs from the interstate natural gas transmission systems, attempting such a clean-up would be a major undertaking with uncertain results and large associated service interruptions. These technologies cannot remove all of the PCBs from the interstate natural gas transmission system to the point where PCBs would no longer be detectable; nor can these technologies be applied to all portions of the pipeline system. Specifically these technologies cannot be applied at compressors stations due to the complexity of piping, valves, rotating equipment and other parts and pieces at these facilities. Importantly, there can be no warranty that the PCBs remaining in the systems after such a clean-up would meet any specified concentration criterion. The clean-up process would include large volumes of waste liquids that would have to be disposed of as PCB waste and could involve natural gas service interruptions. Furthermore, these solvents and surfactant products may not be compatible with gasket materials and seals and could impact the integrity of gasketed flanges and connections resulting in gas leaks and risks of explosions, causing a public safety concern. The solvent and surfactant products introduced in the transmission pipelines would not all be removed during clean-up and some would remain in the systems. Those product residuals could volatilize to the gas stream (solvents) and/or decompose (surfactants) and produce corrosive by-products inside the transmission pipelines.

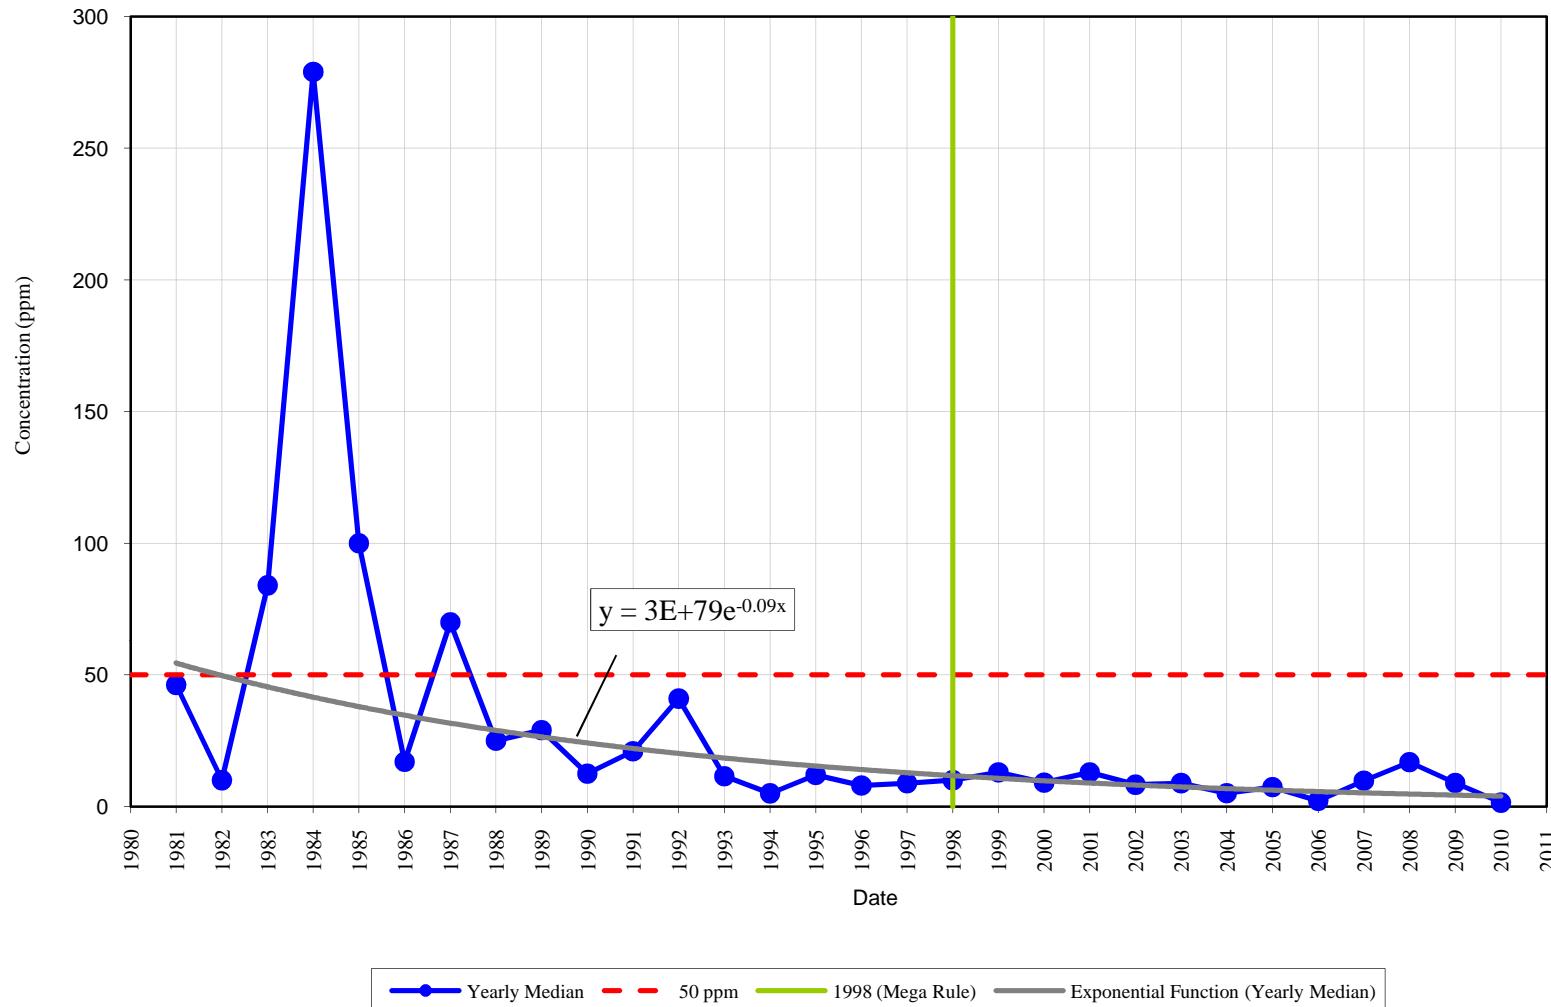

The main technology actively being applied for the removal of PCBs in the interstate natural gas transmission system consists of the inherent and repetitive washing and flushing of pipeline

segments with pipeline liquids. This technology does not add any chemicals or products that would not otherwise be present inside the transmission systems under normal operations. This technology works and continues to gradually remove PCB mass. Pipeline liquids (pipeline condensate and other liquids in the pipelines) are solvents for PCBs. These liquids are periodically pushed through pipeline segments and recovered for disposal. The frequency of periodic pig runs depends upon PHMSA pipeline integrity requirements, pipeline operating conditions and gas scheduling requirements (i.e., customer nominations). The normal formation and removal of pipeline liquids removes PCB residuals and does not introduce chemicals into the pipeline system. This process is conducted with minimal disturbance to pipeline operations thereby minimizing customer disruptions. The removal of pipeline liquids is required for safe operation of pipeline compressor stations and is routinely conducted by trained personnel. These operations are conducted in compliance with applicable laws and regulations to insure worker safety and the proper disposal of PCB waste.

In summary, there are no available, demonstrated and reliable technologies that could perform substantially better than what is being presently done by the interstate natural gas transmission system. PCB residuals remain in the interstate natural gas transmission system and the current technologies that are employed to control and remove PCBs remain the most reliable and effective methods for managing liquids and reduce PCB levels over time.
